Featured sprint

State of the Art Hackathon

A hackathon for artists, musicians and builders, run with SingularityNET and Omega. Pick one of four tracks, form a team of 3 to 4 (or find one on the BASIX job board), and build something BASIX can incubate. Builders submit a GitHub repo shared with BASIX.MARKET; creators submit the finished piece. Everyone submits short documentation with an AI disclosure and a 3-minute video. Judged on technical or creative execution (30%), video and demo clarity (25%), fit to track (25%), and team collaboration and documentation (20%). Prize pool: $500.

Harlem Fine Art & AI for PeaceMeTTa OmegaHack Ready Projects

- 18 Oct, 17:30 — 21 Oct 2026, 23:59 GMT+3
- Online · Nairobi

1.

Hackathons — BASIX Omniversity Incubator" , "📢 Results are in, and the next round is open.

🏆 6 winning teams. $1,000 rolls into the next hackathon.

Our $1,700 prize pool was set for 50 teams.
Six teams earned prizes. The remaining $1,000 carries forward.

Join the State of the Art Hackathon. Free, online, solo or teams of up to 4. Register by Saturday 17 October:
https://basix.market/lms/hackathon/2#register" how to apply to this

You can apply for the State of the Art Hackathon on BASIX.MARKET. Based on the details you shared, registration is free, the event runs online from 18–21 October 2026, and registration closes on Saturday, 17 October 2026, at 5:59 PM EAT.

Since you already build AI, blockchain and full-stack projects, I'd recommend entering with a project that fits one of the four tracks rather than starting something entirely new without checking the rules.

How to apply

1. Open the registration page

State of the Art Hackathon · BASIX.MARKET

Register for the hackathon

Open the page and scroll to the registration section.

2. Choose how you will participate

The announcement says you can participate solo or in a team of up to four. However, the event description also mentions teams of 3–4, so confirm which rule the actual registration form enforces before proceeding.

3. Select a track and prepare your project

The listed tracks are Harlem Fine Art, AI for Peace, MeTTa, and Omega. Review the official requirements and choose the one that best fits your idea.

4. Complete registration

Sign in to BASIX.MARKET, fill in the requested details, select your team and track as applicable, and submit the registration form.

What you should do next

1. Go to the official hackathon page.
2. Click “Sign in to register.” The page confirms that you must sign in to enter.

   BASIX Omniversity Incubator
3. After signing in, follow the registration form and complete the required fields.
4. If the form requires a team, use the BASIX job board mentioned in the event description to find teammates.
5. Save the registration confirmation and check the submission instructions before the sprint starts.

What you need to submit

According to the event description you shared, participants need to prepare:

- A project that fits the selected track.
- A GitHub repository shared with BASIX.MARKET if submitting a software build.
- Short project documentation, including an AI-use disclosure.
- A three-minute demo video.

Projects are judged on execution (30%), demo clarity (25%), track fit (25%), and collaboration and documentation (20%).

My recommendation: First register, then choose the track and project. Don't assume your registration is complete until the platform confirms it.

If you open the registration form and paste its fields or send a screenshot here, I'll help you fill in each answer and choose a strong project for this hackathon.

1.

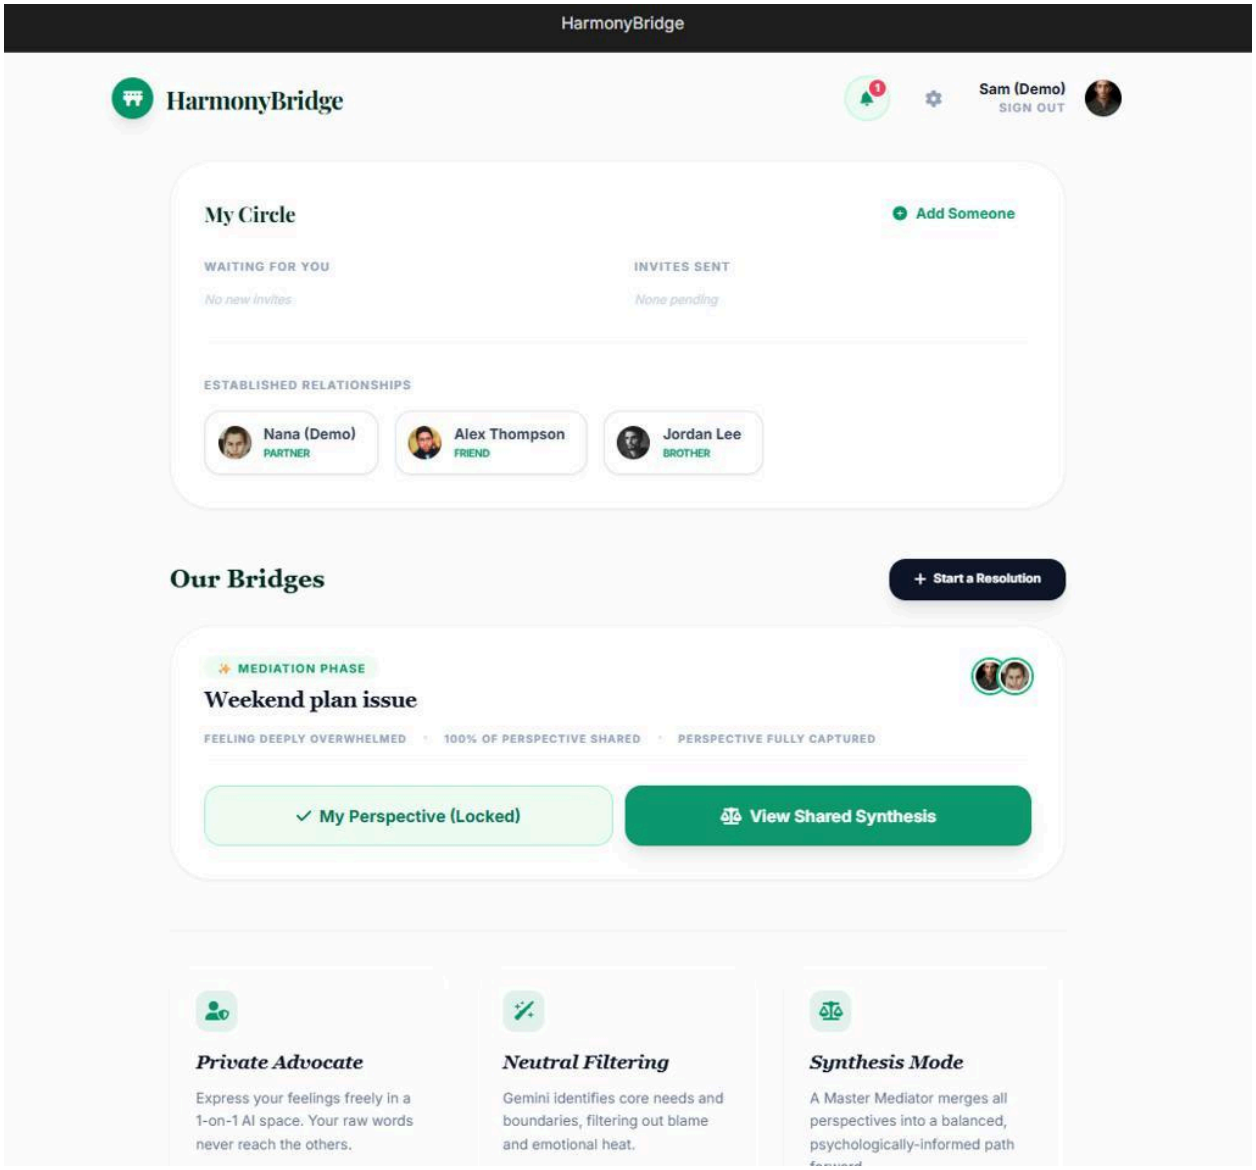

State of the Art Hackathon — BASIX Omniversity Incubator ,,i do not know what to build or work with here

Since you don't yet know what to build, don't create the team just to register and then struggle to find a project. This hackathon requires a team of 3–4 people, and you currently have 1 of 3 members.

Given your experience with MERN, AI, blockchain, and your AgriVerde and AfyaVault projects, I'd focus on an idea that you can build into a working demo in the short sprint from 18–21 October.

The important thing is that this isn't a generic software hackathon. It has four tracks, so the project must fit the track you choose.

Three project ideas I'd consider

My first choice

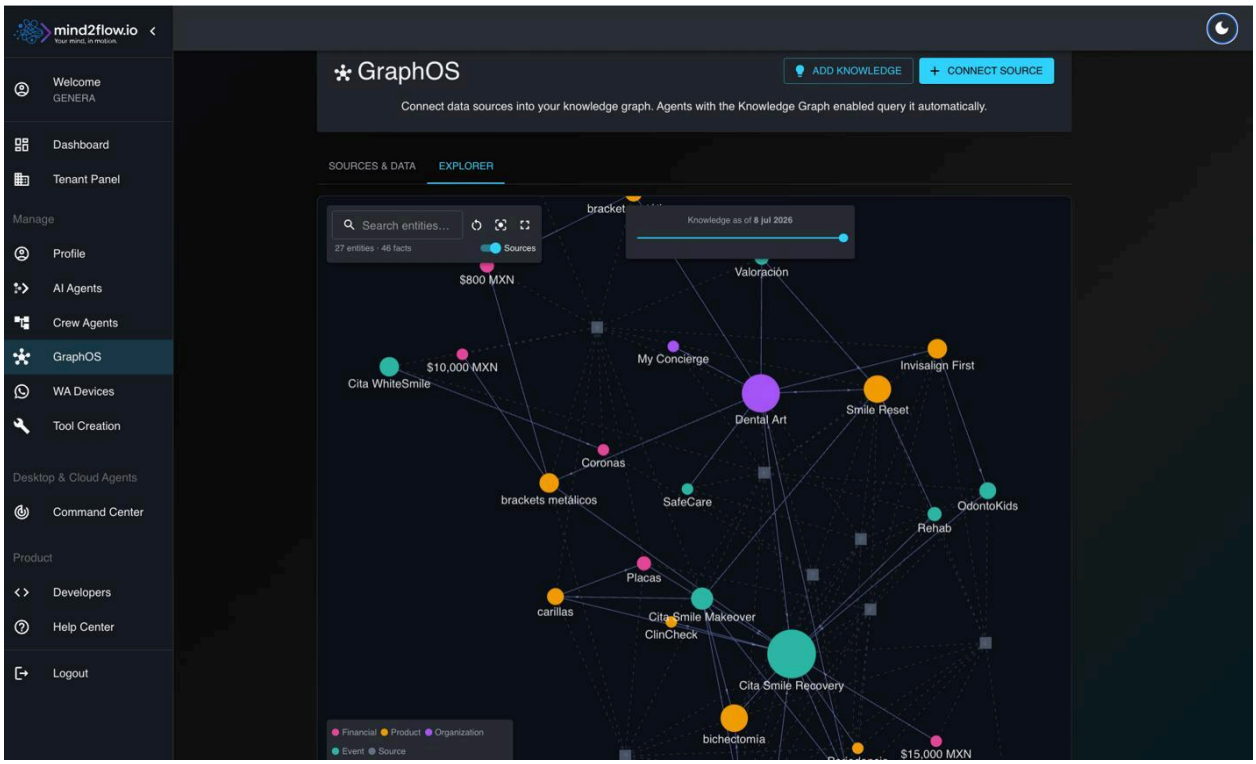

1. PeaceBridge — AI for Peace

An AI-powered platform that helps people navigate disagreements constructively.

- Users submit a disagreement or a tense message.
- AI identifies the main concerns and rewrites inflammatory language into respectful wording.
- It suggests neutral questions and possible common ground.
- Users can compare alternative responses before sending a message.

Build: React, FastAPI, and an LLM API. Include example scenarios so the demo works even if live AI fails.

Why it fits: a clear AI for Peace concept with an easy-to-demonstrate user journey.

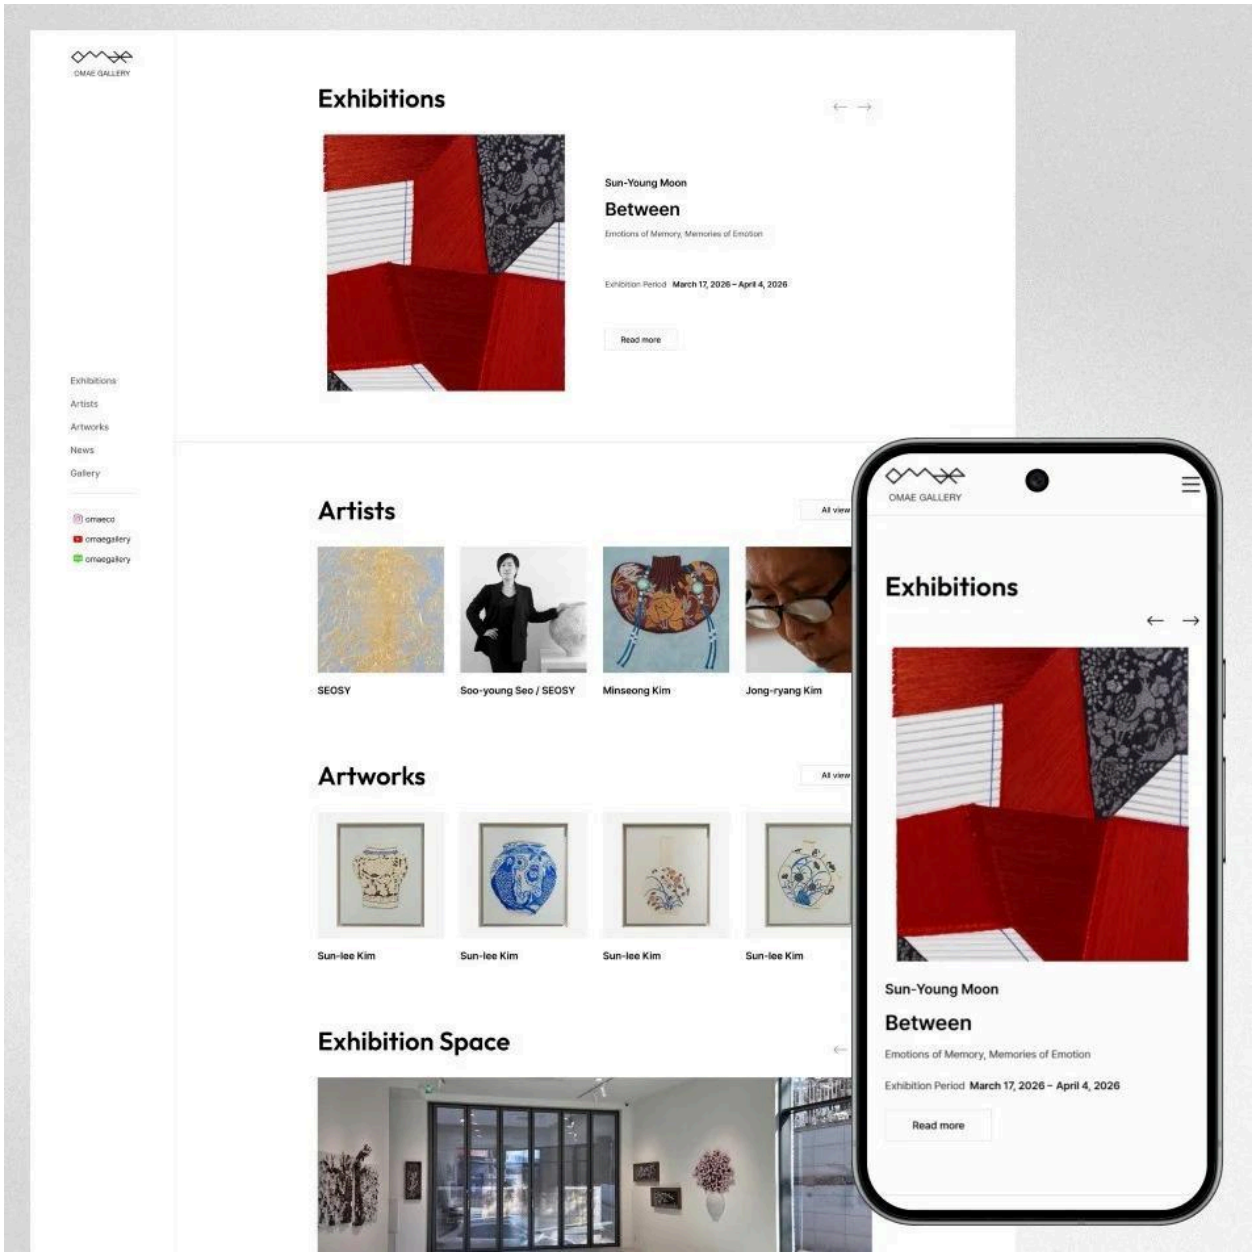

2. ContextGraph — MeTTa

A small knowledge system that represents facts and relationships, then uses symbolic reasoning to answer questions.

- Add facts about a fictional community, organization, or project.
- Connect people, resources, and events.
- Ask questions and demonstrate how the system derives answers from stored facts.

Build: A simple web interface with a MeTTa reasoning layer.

Why consider it: technically interesting, but you would need to learn the required MeTTa tooling and verify the track rules.

3. ArtStory AI — Harlem Fine Art

A digital gallery where artists publish work with stories explaining its cultural context, inspiration, and meaning.

- Artists create profiles and upload artwork.
- AI helps draft artwork descriptions from the artist's own notes.
- Visitors explore themes, discover artists, and curate collections.

Build: MERN with image storage and an optional AI description feature.

Why consider it: suitable if you want a more visual, creative product rather than a technically complex AI system.

What I would choose in your position

I'd start with PeaceBridge, provided the official AI for Peace track permits this kind of application. It lets you demonstrate full-stack development and AI integration without needing to build an entirely new blockchain protocol or learn a new programming language during a three-day sprint.

One important caveat: the exact track-specific requirements and judging expectations should be checked before committing to the idea.

What to do on the registration page

You have two options:

- Create a new team: if you can recruit two suitable teammates before submission.
- Join with a code: if you find an existing team that needs another developer.

I would recruit people with complementary skills: one frontend/full-stack developer, one AI or backend developer, and optionally someone focused on UX, testing, and the demo. You can cover multiple roles yourself, depending on who joins.

One question before we settle on the project: Do you want to build something primarily technical, or would you rather build a product with a strong visual/demo experience?

1. What kind of project interests you most?

Technical — AI, reasoning, agents, or backend engineering
Visual — polished interface, creative product, and strong demo
Social impact — peacebuilding or a real community problem
Whichever gives me the strongest chance of placing

2. What is your team situation?

I need to find two or three teammates
I have people I could invite
I'd prefer to find an existing team
Help me decide
"📢 Results are in, and the next round is open.

🏆 6 winning teams. $1,000 rolls into the next hackathon.

Our $1,700 prize pool was set for 50 teams.
Six teams earned prizes. The remaining $1,000 carries forward.

Join the State of the Art Hackathon. Free, online, solo or teams of up to 4. Register by Saturday 17 October:
https://basix.market/lms/hackathon/2#register" had said there is solo still the suggested problem i have dought on them

You're right to question it. The announcement says “solo or teams of up to 4,” but the registration page you opened explicitly says:

- Teams must have 3–4 members.
- Your account currently counts as 1 of 3.
- You must create or join a team and reach at least three members before submitting.

Those instructions conflict. I would trust the registration page for what the platform currently enforces, but I wouldn't assume solo participation is impossible until BASIX clarifies whether solo builders can register and submit independently.

And your second concern is valid, too: the project ideas I suggested were preliminary concepts, not verified winning strategies. We should check the actual track requirements before committing your time.

What I'd do now

Before choosing a project or recruiting teammates, send the organizers this short clarification.

Hi BASIX team, I saw the announcement saying the State of the Art Hackathon is open to solo participants or teams of up to four. However, the registration page says teams must have 3–4 members and requires at least three before submitting.

Could you please clarify whether solo participation is allowed, and if so, how a solo builder should register and submit a project?

I'd also appreciate clarification on the specific requirements for each track so I can choose an appropriate project.

Thank you.

You can contact them through the official BASIX website, which lists `office@basix.market` for general inquiries.

BASIX Omniversity Incubator

My advice: Don't recruit people just to satisfy a potentially inconsistent form. First confirm the rules. If solo entry is genuinely allowed, we can choose a tightly scoped project you can build independently. If three members are mandatory, we can plan around that instead.

1.

State of the Art Hackathon — BASIX Omniversity Incubator"

Now we have a clearer picture. The registration form explicitly says “Teams take 3–4 people with no solo path.” So, despite the promotional announcement, the current registration workflow requires a team of at least three people.

The form also reveals something important: you must choose a track, describe the problem you're solving, state your project's stage, and provide a GitHub repository. Let's work out what to enter rather than filling it with an unvalidated idea.

1. What to enter in the form

Field	What I recommend
Team name	Choose a name after deciding on the project
Track	Select the track that best matches the verified requirements
Which problem are you solving?	A specific, clearly defined problem statement
Project stage	Honestly select your current stage

GitHub repository	Use an existing repository if appropriate, or clarify whether a new/empty repository is accepted

The listed tracks are Harlem Fine Art, AI for Peace, MeTTa, Omega, and Hack Ready Projects.

2. Let's choose a project based on the actual tracks

I would not commit to PeaceBridge or another idea yet. We need to establish what each track expects, what technologies are required, and whether projects must be new or can be existing builds.

Here is the most practical next step:

- Open the official hackathon details.
- Look for the track descriptions, rules, required technologies, and submission criteria.
- Share those details here if the page doesn't make them clear.

Once we have them, I can help you select a feasible project, define its MVP, decide what to build during the sprint, and prepare a credible problem statement for the registration form.

One thing you should do immediately: If you want to participate, start looking for two teammates while we evaluate the tracks. Registration closes on 17 October at 5:59 PM EAT, so you have limited time to assemble a team.

,for the team side leave it for now , let first idenfy what we can build by finding a problem that we can work on here and define it fully,

Let's leave the team registration aside and approach this as a product discovery exercise. We should identify a real problem, understand who experiences it and why existing solutions fall short, then define a product that is feasible to build and demonstrate during the 18–21 October hackathon.

I don't want us to pick an idea just because it sounds impressive or has AI in the name. The project needs to satisfy three things:

- A real problem: a clearly identifiable user has a meaningful problem that existing tools don't adequately solve.
- A strong track fit: the idea directly addresses one of the hackathon's tracks, rather than being a generic app retrofitted to fit.
- A demonstrable solution: we can build a working end-to-end MVP in the available time, with a clear way for judges to see that it works.

Given your full-stack, AI and blockchain background, we can consider technically ambitious ideas, but the problem should determine the technology—not the other way around.

1. The problem spaces worth investigating

Rather than generate ten random app ideas, I'd investigate these three problem areas first. Each has a distinct user, a problem we can test, and a potential connection to the hackathon.

A. Independent artists struggle to make their work discoverable and commercially usable

Potential track: Harlem Fine Art

Artists can have finished work but still struggle to communicate its context, present a coherent portfolio, and help potential buyers understand its value.

Problem to investigate: Can we help an artist turn an artwork and its story into a compelling, discoverable exhibition entry without taking control of the artist's voice or rights?

B. People struggle to resolve misunderstandings before they escalate

Potential track: AI for Peace

In community groups, student organizations, and online discussions, people can misinterpret messages, respond defensively, and struggle to find common ground.

Problem to investigate: Can we help two parties identify the actual disagreement, distinguish facts from assumptions, and find a mutually acceptable next step?

The key is supporting dialogue—not having AI decide who is right.

C. AI systems can produce answers without making their reasoning inspectable

Potential track: MeTTa

When a system answers a question, users may not know which facts support the answer, which relationships were inferred, or where the evidence is missing.

Problem to investigate: Can we build a small reasoning system that answers questions from a defined knowledge base and exposes the facts and rules behind each conclusion?

This is a stronger fit if the track specifically rewards MeTTa-based symbolic reasoning rather than a conventional chatbot.

These are hypotheses, not established findings. We'd need to validate the actual pain points with users and check the track rules before choosing one.

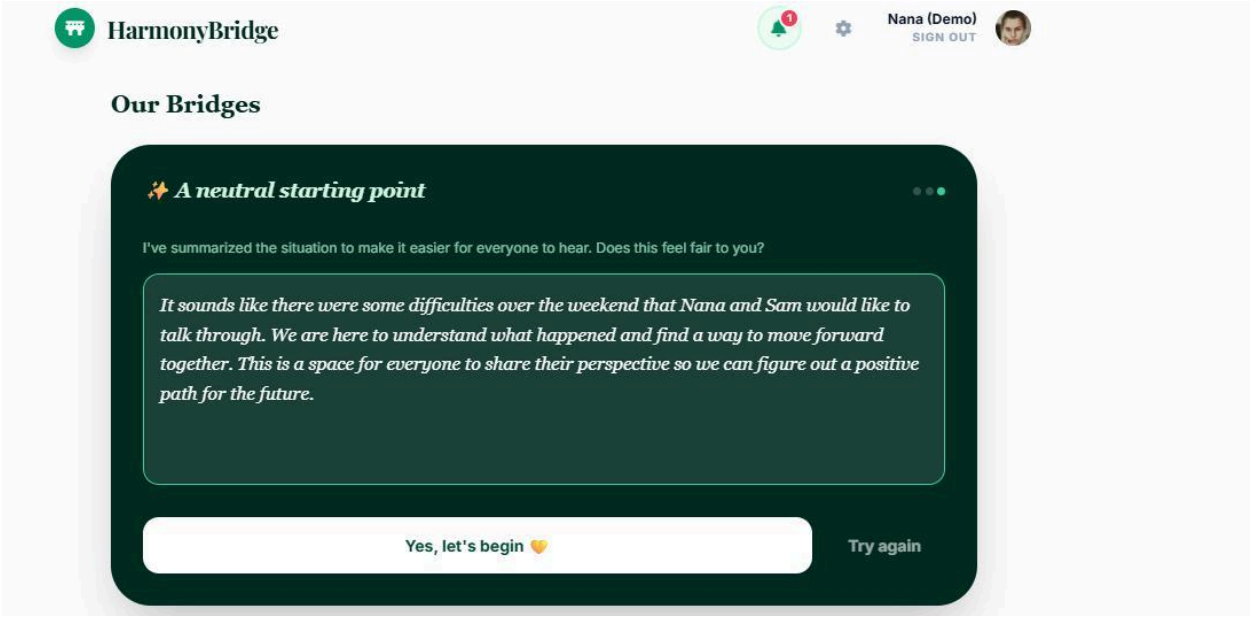

2. Let's develop one candidate into a complete problem definition

My provisional recommendation is an AI for Peace project focused on helping people work through disagreements constructively. We can use a working name, CommonGround, while we investigate whether this is the strongest opportunity.

Candidate 01 · AI for Peace

CommonGround

A guided conflict-understanding and resolution tool

devpost.com

The core problem

When two people disagree, each person often sees the situation from their own perspective. Important context gets lost, assumptions become mixed with facts, and conversations can become more hostile instead of moving toward a solution.

Existing messaging tools help people communicate, but they generally don't provide a structured process for understanding both sides of a disagreement and identifying practical next steps.

3. Define the problem precisely

Who experiences it?

- Student groups working through disagreements about responsibilities or decisions.
- Community organizers managing conflicting viewpoints.
- Small teams dealing with misunderstandings about commitments and expectations.
- Individuals who want to respond constructively to a tense conversation.

When does it happen?

For example, imagine a university project group. One member believes another has failed to complete their assigned work. The other believes the deadline and responsibilities were never clearly agreed upon.

The discussion shifts from the actual task to personal accusations. Neither person has a clear way to separate what happened, what each person assumed, and what needs to happen next.

Why existing approaches may fall short

- Direct messaging can make misunderstandings worse.
- Asking a friend to mediate may introduce bias or expose private information.
- Generic AI chatbots can suggest polite wording, but may not systematically represent both parties' perspectives or distinguish established facts from unverified claims.
- Formal mediation may be unnecessary or inaccessible for everyday, low-stakes disagreements.

These are proposed problem areas to validate, not claims that every existing tool fails in these ways.

4. What exactly would we build?

CommonGround would not be another chatbot that simply says, “Be respectful.” It would guide the user through a structured process.

Step 1 — Describe the disagreement

The user explains what happened in their own words. They can remove names and other identifying information before submitting.

Step 2 — Separate facts from assumptions

The system organizes the account into reported events, interpretations, unanswered questions, and the user's concerns. It must not present allegations as verified facts.

Step 3 — Understand both perspectives

The user can add the other party's perspective, if available and shared voluntarily. The system identifies differences, overlapping concerns, and missing information without pretending to know what the other person thinks.

Step 4 — Find common ground

The system proposes neutral questions, possible compromises, and a few practical next steps. Users can reject or edit suggestions.

Step 5 — Produce an agreement draft

The result is a concise summary of the unresolved issue, agreed facts, open questions, and proposed actions, ready for the people involved to review.

5. Define the MVP and what we will not build

The hackathon runs for roughly three days, so the first version should remain narrow.

Build in the MVP	Leave out initially
Conflict-description form	Automatic WhatsApp integration
Structured analysis of a disagreement	Public conflict reporting
Fact-versus-assumption breakdown	AI deciding who is right
Common-ground suggestions	Blockchain-based dispute records
Editable resolution summary	Complex multi-agent systems

Three or four test scenarios	A full social network

Potential stack: React for the interface, FastAPI for the backend, and an LLM API for structured analysis. We can use a simple database—or temporary in-memory storage for the initial demo—rather than spending the sprint building infrastructure.

The AI must not claim to be a professional mediator. Cases involving threats, abuse, coercion, or immediate danger should be directed toward appropriate human support rather than handled as ordinary disagreements.

6. How would we prove it works?

We should prepare three test scenarios before building:

1. A university project team disagreeing about task ownership.
2. Two community members misunderstanding a message.
3. A group disagreeing about how to allocate a limited resource.

For each scenario, check whether the system:

- Correctly identifies the central disagreement.
- Distinguishes what is reported from what is inferred.
- Represents the perspectives provided without inventing the missing side.
- Produces actionable, non-inflammatory suggestions.
- Makes it easy to correct a misleading summary.

We can measure these outcomes against a manually reviewed checklist. We should not claim that the product reduces real-world conflict unless we later conduct appropriate user testing.

7. Before we commit: validate the problem and the track

This is where I would be strict. A good product concept is not automatically a good hackathon entry. We need to check the exact track expectations, whether a similar solution already exists, and whether users actually experience the problem as described.

The official BASIX hackathon page lists the tracks, but the public page I could verify does not expose enough detailed track-specific rules to establish which one would be best. CommonGround is therefore a candidate, not a final selection.

Here are the questions I would investigate next:

- Do people actually struggle with this problem often enough to use a dedicated tool?
- What do they currently do when a disagreement escalates?

- Would a structured tool genuinely help, or would it feel intrusive?
- What would make the solution meaningfully different from simply asking a general-purpose AI chatbot?
- Does the AI for Peace track reward practical conflict-resolution tools, or does it have a more specific challenge?

My recommendation: Keep CommonGround as our first candidate, but compare it against at least one strong alternative before committing. The next step should be evidence-based problem validation and a track-fit check—not coding yet.

Harlem Fine Art & AI for Peace

MeTTa Foundation

Omega AI Agents, Choose a challenge AI as creative partner Legacy in motion The borderless studio Peace love unity Co-own your work The Glass Box Agent The Agent That Grows Up MeTTa Core Challenge Two Agents One Truth The Agent Without Borders BASIX.MARKET - Mature Build" pet chose everything and fill everything for team never mind if register alone will be taken as solo already contacted them and for luma jelp choose better date

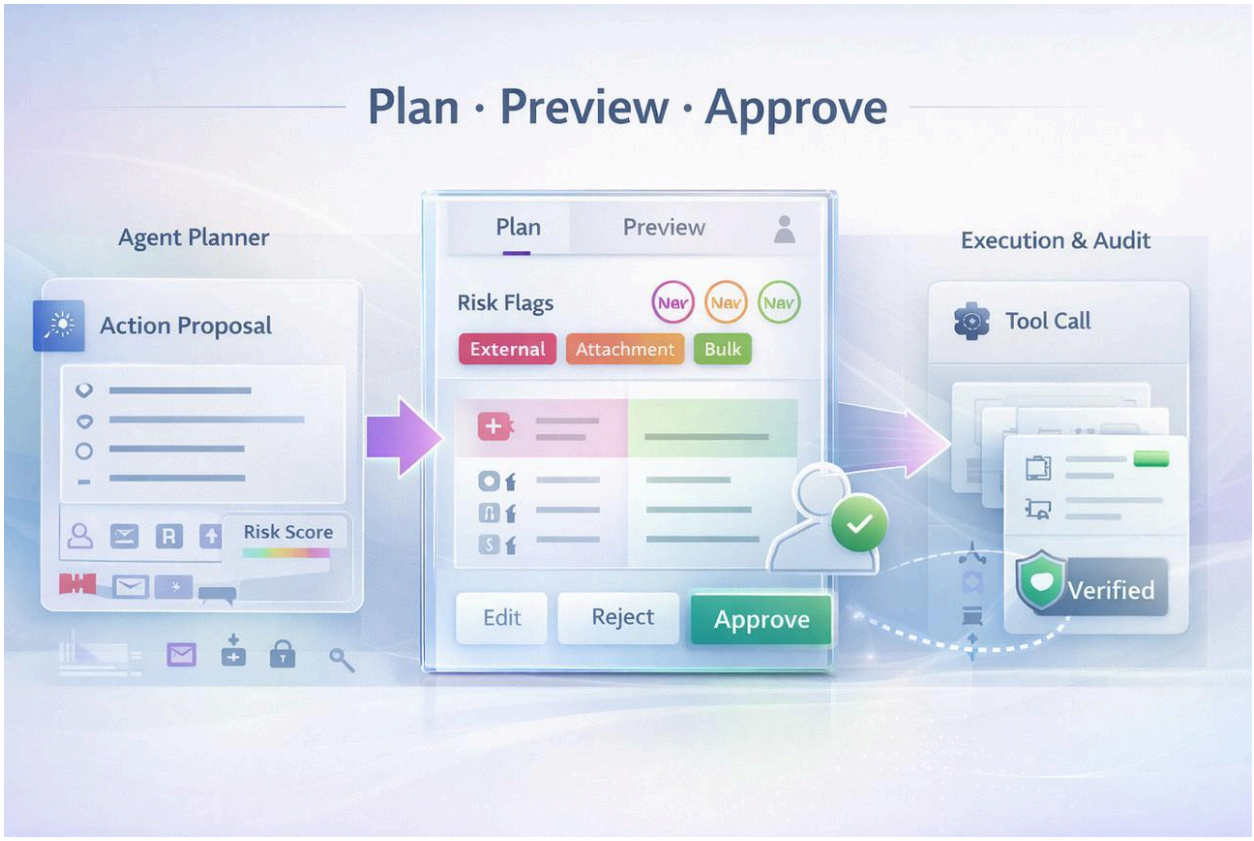

I'll choose the project direction and give you ready-to-enter answers for the BASIX registration form, including the team name, track, challenge, problem statement, project stage, and GitHub field.

For the separate Lisbon buildathon, we'll choose the session based on which gives you the best preparation time and practical chance of attending—not just which date looks better.

One important distinction: the BASIX hackathon is an online competition, while the AI Omega Developer Buildathon you've shared is an in-person event in Lisbon, Portugal. They are separate registrations.

1. My selected BASIX project

I'd choose Omega AI Agents → The Glass Box Agent as the first option to verify in the form. It gives us a specific engineering problem to solve rather than another general-purpose chatbot.

ClearTrace — The Glass Box Agent

An explainable, auditable AI agent

Problem: People may not be able to verify why an AI agent made a recommendation, which evidence it used, or what actions it took.

Solution: Build an agent that shows its task plan, supporting evidence, proposed actions, and a chronological action log. It asks the user for approval before carrying out consequential actions.

What we'd actually build

The demo will use a bounded task—for example, reviewing supplier invoices against purchase-order records for a small business.

1. The user uploads a sample invoice and purchase-order data.
2. The agent extracts the relevant fields and checks them against the records.
3. It flags discrepancies and shows the evidence behind each finding.
4. It proposes a next action, such as requesting clarification from the supplier.
5. The user approves or rejects the proposal.
6. The system records the decision and the agent's actions in an audit log.

This is a practical starting point for a transparent agent, not a claim that AI reasoning itself can be fully exposed. We'll show verifiable inputs, rules, evidence, decisions, and action records.

2. Fill in the BASIX registration form

Use these choices as your proposed registration details.

FIELD 3

Challenge

The Glass Box Agent
Copy

Select this challenge if it appears under Omega AI Agents. If it is listed under another track, pause and share the options before submitting.

FIELD 4 — PROBLEM STATEMENT

Small businesses increasingly use AI tools to assist with operational decisions, but it can be difficult to verify the evidence behind an AI-generated recommendation or reconstruct what the system did. ClearTrace addresses this trust and accountability gap by building an AI agent that reviews supplier invoices against purchase-order records, identifies discrepancies, explains findings using traceable evidence, proposes corrective actions, and records user approvals and agent activity in an auditable log. The goal is to make AI-assisted workflows more transparent, reviewable, and controllable.

Copy problem statement

FIELD 5 — PROJECT STAGE

Just an idea

Select this if you haven't started implementing ClearTrace yet. If you begin designing the system or writing code before submitting, select the stage that accurately describes your progress.

FIELD 6 — GITHUB REPOSITORY

Create a repository called `cleartrace-agent` under your GitHub account, then enter its actual URL. Do not enter a fabricated URL or an unrelated project just to complete the field.

Create GitHub repository

Proposed technical implementation

- Frontend: React.
- Backend: Python and FastAPI.
- Agent integration: Omega AI Agents, using the official SDK and documentation provided by the organizers.
- Data: Synthetic invoices and purchase orders for the demo.
- Audit trail: Structured action records with evidence references, timestamps, and approval status.

The Omega integration is essential to the track fit. We should confirm the required SDK and agent capabilities before deciding how to implement it. We can build the rest of the application around a small, testable workflow.

Do not claim that the project already has a working prototype if it doesn't. We can turn the idea into a working demo during the buildathon.

3. Which Lisbon buildathon date should you choose?

Week 1 — 23–24 October

Friday–Saturday · HealthHub, Unicorn Factory Lisboa

Less time to prepare, but you'd get to build and showcase earlier.

My recommended session

Week 2 — 29–30 October

Thursday–Friday · Fintech House, Unicorn Factory Lisboa

Gives you six extra days to prepare, investigate the Omega tooling, and develop a stronger prototype.

Open the Luma registration page

The organizer lists both sessions as free, with registration requiring approval and only 20 developer seats per session.

⚠

LISBON · Luma

Important before you accept: this is an in-person event in Portugal, not an online attendance option. Since you're in Kenya, check whether you can realistically obtain the necessary travel authorization, flights, and accommodation. The announcement mentions meals and refreshments, but doesn't promise travel funding.

My recommendation is to request Week 2, 29–30 October, if you can make the trip. It gives you more preparation time, but the extra days are not worth choosing it if travel is financially or logistically impossible.

4. Your next actions

1. Fill in the BASIX form using the proposed ClearTrace details, verifying the challenge appears under the selected track.
2. Create the GitHub repository and enter its real URL.
3. On Luma, select Week 2 and request approval if you can attend in person.
4. Before coding ClearTrace, verify the Omega integration requirements and build a small proof of concept.

The aim is to arrive with a clear problem, a realistic prototype plan, and a demo that shows exactly why the product is useful.

The challenges option available, "Choose a challenge

Two Agents One Truth

The Agent Without Borders

BASIX.MARKET - Mature Build"

Choose Two Agents One Truth. It is the strongest fit for a focused, demonstrable AI agent project, provided the challenge requirements support comparing agents' findings or resolving conflicting outputs.

I'd update the registration details as follows:

- Team name: ClearTrace Labs
- Track: Omega AI Agents
- Challenge: Two Agents One Truth
- Project name: ClearTrace
- Project stage: Just an idea, if you haven't started building it.

Refined problem statement

AI agents can produce conflicting answers or recommendations, leaving users unsure which conclusions are supported by evidence. ClearTrace is a multi-agent verification system that

assigns two AI agents to independently analyze the same set of supplier invoices and purchase-order records. A verification layer compares their findings, identifies disagreements, checks claims against source data, and presents the supporting evidence and unresolved issues for human review. Rather than assuming either agent is correct, the system makes discrepancies visible and helps users reach evidence-based decisions.

Why this is a good direction: It gives us a clear demonstration: two agents analyze the same data, disagree on a finding, and a verification layer checks the evidence instead of blindly trusting either response.

One important caveat: we should inspect the official challenge brief before finalizing the concept. If Two Agents One Truth requires a particular interaction between agents, we should build around that requirement rather than assume this interpretation is exactly what the organizers expect.

BASIX

Hackathons

Registration open
Online
18 Oct, 17:30 — 21 Oct 2026, 23:59 GMT+3
State of the Art Hackathon
A hackathon for artists, musicians and builders, run with SingularityNET and Omega. Pick one of four tracks, form a team of 3 to 4 (or find one on the BASIX job board), and build something BASIX can incubate. Builders submit a GitHub repo shared with BASIX.MARKET; creators submit the finished piece. Everyone submits short documentation with an AI disclosure and a 3-minute video. Judged on technical or creative execution (30%), video and demo clarity (25%), fit to track (25%), and team collaboration and documentation (20%). Prize pool: $1000.

Which problem you're solving
Small businesses increasingly use AI tools to assist with operational decisions, but it can be difficult to verify the evidence behind an AI-generated recommendation or reconstruct what the system did. ClearTrace addresses this trust and accountability gap by building an AI agent that reviews supplier invoices against purchase-order records, identifies discrepancies, explains findings using traceable evidence, proposes corrective actions, and records user approvals and agent activity in an auditable log. The goal is to make AI-assisted workflows more transparent, reviewable, and controllable.

Edit team details
BASIX Omniversity · Dev LMS · badges by Open Badges v2 · DICE-owned · Terms · Privacy

Your registration is now created under ClearTrace Labs, with Omega AI Agents → Two Agents One Truth selected. The project direction is promising, but the current registration details need two improvements before kickoff.

1. GitHub: Your current entry is `https://github.com/Edwin420s`, which is your profile, not a project repository. Create a dedicated repository for ClearTrace and update this field if the form allows it.
2. Challenge fit: Refine ClearTrace around two agents independently examining the same evidence, then resolving disagreements through verifiable checks. That makes the connection to Two Agents One Truth much clearer than a general AI audit-log application.

Your dashboard says the submission is due 20 October 2026 at 17:59 EAT, with the build starting 18 October at 17:30 EAT. That gives you roughly two days from kickoff to submit, so scope control is critical.

1. Fix the GitHub field first

Your current field contains your GitHub profile:

`https://github.com/Edwin420s`

Create a dedicated repository instead:

Repository name: `cleartrace-agent`

Suggested description: Evidence-grounded multi-agent verification system.

Create the repository on GitHub

Update the BASIX team details with the repository's actual URL once it exists. Make sure the repository is accessible to the organizers and that you can share it with BASIX.MARKET as required.

2. The MVP we should build

ClearTrace — Two Agents, One Evidence-Based Result

Input data

Invoice + purchase order + supplier record

Agent A

Extracts fields and identifies discrepancies.

Agent B

Independently checks records and validates claims.

Verification engine

Compares outputs against source data and flags disagreements.

Final evidence report

Agreements, conflicts, supporting evidence and unresolved questions.

The important technical distinction is that two agents agreeing does not automatically make an answer true. The system should compare their conclusions against the underlying records and explicitly flag cases that cannot be resolved.

3. Our build priorities

Priority	Deliverable
1	A working invoice and purchase-order dataset
2	Two genuinely separate agent analyses
3	A comparison and evidence-verification engine
4	A clean dashboard showing agreements and conflicts
5	A working example with a deliberately introduced discrepancy
6	README, AI disclosure, documentation and a three-minute demo video

Use Omega's required agent tooling where specified by the organizers. Don't spend the whole sprint on elaborate infrastructure; the visible, testable workflow is the core deliverable.

4. Keep these deadlines in view

- 16 October, 17:59 EAT: Registration closes.
- 18 October, 17:30 EAT: Build starts.
- 20 October, 17:59 EAT: Submission deadline.
- 21 October, 23:59 EAT: Event ends.

Your dashboard confirms the team is created, but it still shows only one member and requires at least three. So the registration record exists, while eligibility to submit as a complete team remains unresolved.

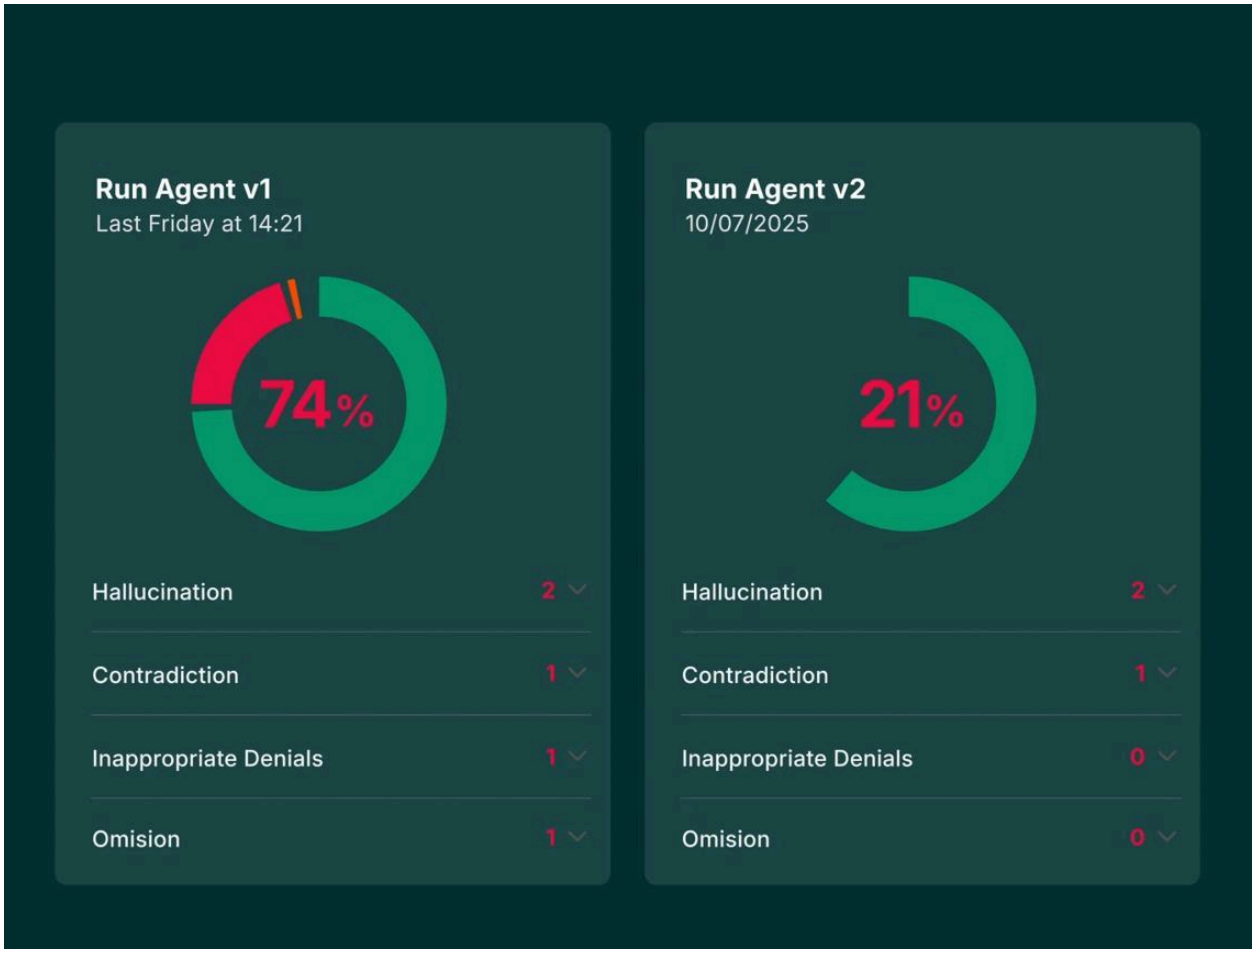

My recommendation: Create the repository now, then use the time before kickoff to inspect the official Omega AI Agents documentation and prepare the test dataset and application skeleton. That gives ClearTrace a much better chance of becoming a working project rather than just a concept.

Between this project and agriguide whivh pne should i go with the agriguide the previous project

My recommendation is to go with ClearTrace for the BASIX State of the Art Hackathon, while keeping AgriGuide as a separate project that you can develop further for other hackathons and your broader portfolio.

However, there's one important condition: if AgriGuide can be adapted to the Two Agents One Truth challenge more naturally than ClearTrace, it may be the stronger option. Let's compare them properly.

ClearTrace vs AgriGuide

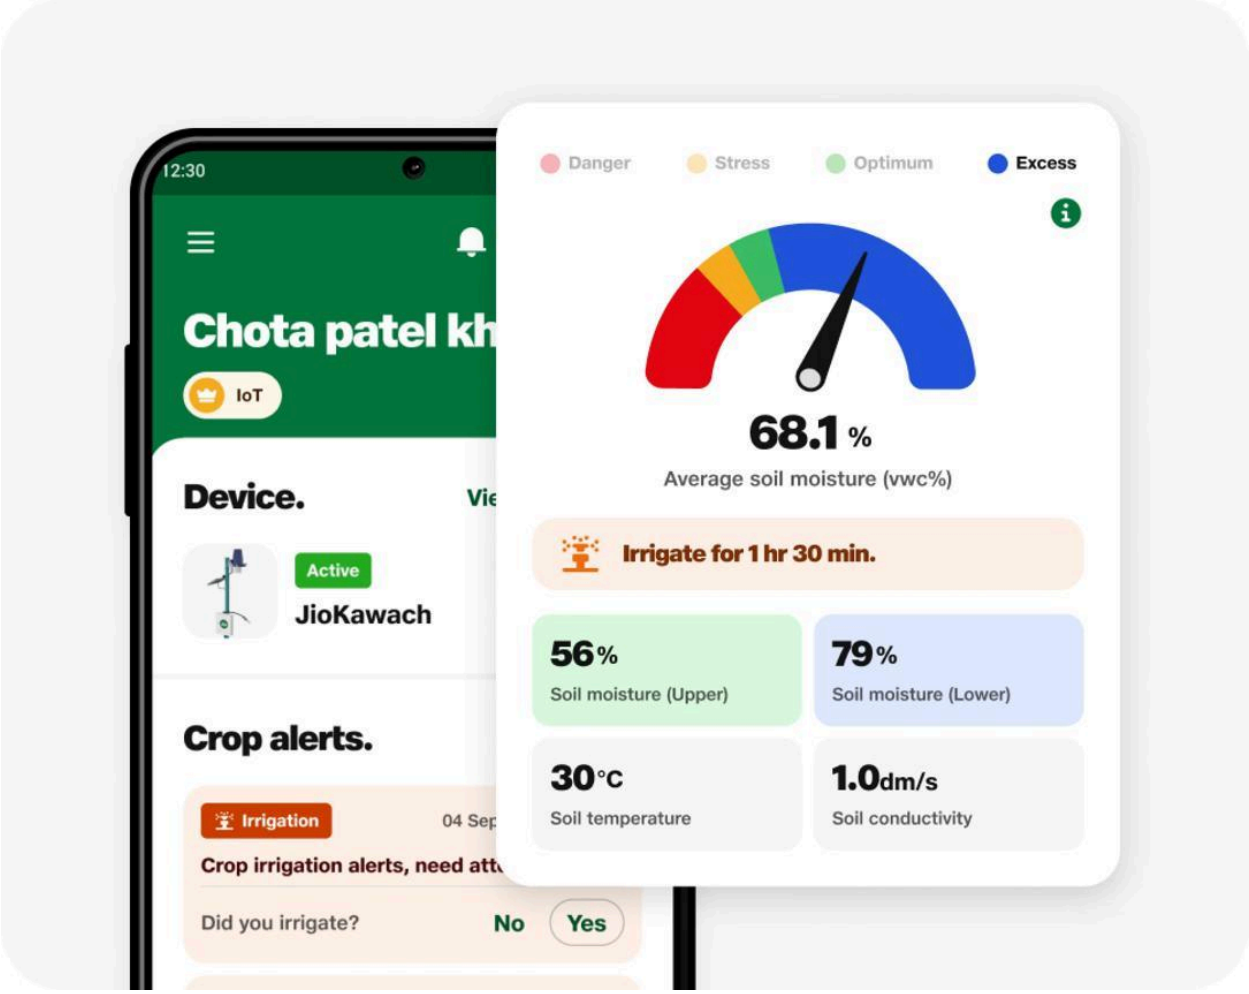

ClearTrace

Best initial fit

Two AI agents independently examine supplier invoices and purchase orders, then compare findings against the source data to identify discrepancies.

- Directly demonstrates the Two Agents One Truth concept.
- Small, self-contained dataset.
- Easy to demonstrate a disagreement and evidence-based resolution.
- Can be built without physical hardware.

AgriGuide

An agricultural decision-support platform that helps farmers understand field conditions, monitor soil moisture and weather, and make better irrigation decisions.

- Addresses a meaningful agricultural problem relevant to Kenya.
- Fits your existing agricultural technology interests.
- Can combine AI, sensor data and practical farm recommendations.
- Needs a specific connection to the selected Omega challenge to be competitive here.

My assessment

Criterion	ClearTrace	AgriGuide
Fit with Two Agents One Truth	Strong	Needs adaptation
Feasibility in the short sprint	High	Depends on scope
Distinctiveness	Moderate–high if verification is rigorous	Potentially high with locally relevant agricultural data
Hardware dependency	None	None if using simulated data; sensors are optional
Long-term portfolio value	AI agents and trustworthy automation	AI, agriculture and possibly IoT

These are preliminary assessments, not predictions of the judging outcome.

The deciding factor

If you choose AgriGuide, I would not submit a generic crop-advice chatbot. I would reshape it into something like AgriGuide Verify:

- Agent 1 analyses soil moisture, crop requirements and available weather data.
- Agent 2 independently checks the proposed irrigation recommendation against crop thresholds and the same source data.
- A verification layer identifies conflicting recommendations and explains the evidence.
- The farmer receives a clear irrigation recommendation, confidence limitations and an explanation of what needs checking.

That would connect the agricultural problem directly to the two-agent challenge while giving the project a more distinctive real-world purpose.

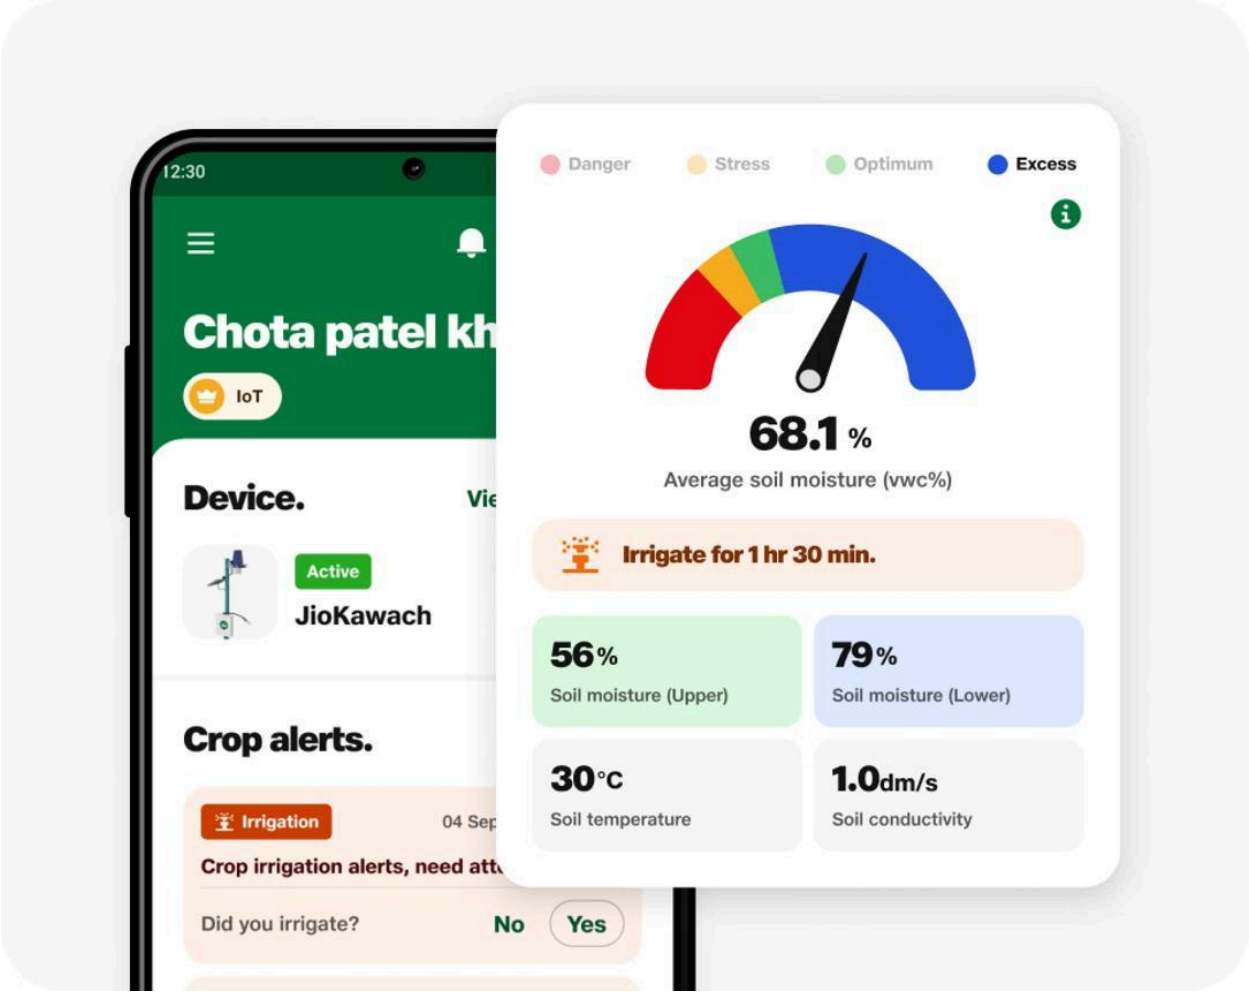

My final advice: Choose ClearTrace if your priority is building a focused demo with the least scope risk. Choose AgriGuide Verify if you can reuse a meaningful amount of existing AgriGuide work and want the entry to build on your agricultural technology direction.

Before I make the final call, one question: How far had you already developed AgriGuide—was it just an idea, a designed UI, or did you already have working code?

I have a working prototype which i was number 5 in last hackathonThen I'd lean toward AgriGuide for the BASIX.MARKET hackathon, especially since you already have a working prototype and finished 5th in your previous hackathon with it.

That changes the decision. You're not starting from zero, and you have something you can improve, demonstrate, and validate under a short deadline.

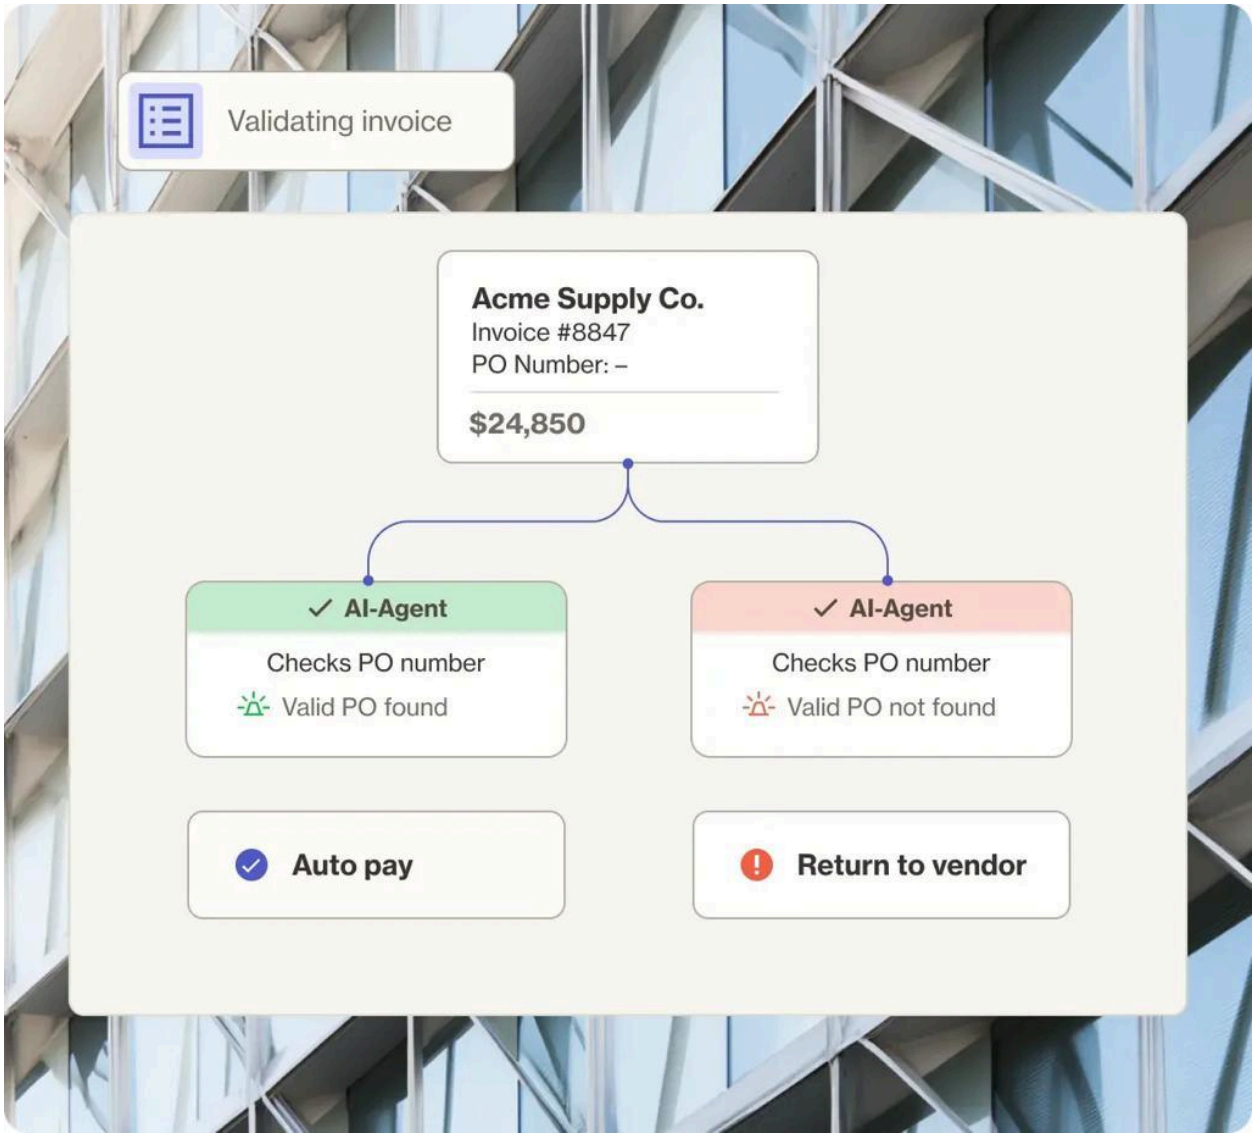

AgriGuide vs. ClearTrace

AgriGuide — my recommendation

Existing prototype

- Builds on a product you've already tested in a hackathon.
- Gives you a concrete problem to demonstrate: helping farmers make better agricultural decisions.
- Could stand out through reliable AI recommendations, local agricultural context, and transparent evidence.
- Main risk: it must fit the hackathon challenge, not simply be a general farming app.

ClearTrace

New build

- Naturally fits the Two Agents One Truth challenge.
- Has a clear verification workflow and measurable results.

- But you'd be starting a new product under a tight deadline, with more implementation risk.

How I would adapt AgriGuide

If you're entering the Omega AI Agents — Two Agents One Truth challenge, don't just submit the existing prototype unchanged. Make the two-agent verification capability the central innovation.

Farmer's question

“Should I irrigate my crop today?”

Agent 1

Recommends an irrigation action using available soil, weather and crop data.

Agent 2

Independently checks the recommendation against source data and agronomic rules.

Verification layer

Shows agreements, disagreements, supporting evidence, and missing data.

Explainable recommendation for the farmer

Action, evidence, uncertainty, and whether human review is needed.

The important distinction is that two agents agreeing does not automatically make a recommendation correct. AgriGuide should also verify claims against actual data and explicit rules.

Before we commit, one important detail

Since AgriGuide already reached fifth place, I want to build on what you have rather than recommend unnecessary rewriting.

What does your current AgriGuide prototype already do?

1. What is already working?

Working app with functional features
Partially working prototype
Demo/prototype with mostly simulated functionality

2. Which features does it have?

Crop recommendations
Weather-based advice
Soil or irrigation monitoring
AI chatbot or agent
Crop disease detection
Other features

3. What technology did you use?

MERN stack
Python / FastAPI / AI backend
Mixed stack
Other or not sure
Build the hackathon strategy

My current recommendation: keep AgriGuide, reuse the working prototype, and add a genuinely verifiable two-agent workflow—provided the challenge rules allow that direction.

Given your AgriGuide win and your experience building an Omega-powered agricultural decision agent, I'd position your State of the Art Hackathon entry around auditable AI agents that make evidence-based decisions rather than starting an unrelated project.

For the BASIX registration, I'll use your existing team identity, Nexora AI, and choose the challenge that best matches your strengths. For the Lisbon event, I'll prioritize the session that gives you the strongest practical opportunity to build on AgriGuide, learn from the Omega developers, and showcase your work.

One important distinction: the Lisbon Buildathon and the State of the Art Hackathon are separate events, so you should treat their registrations independently.

Here is how I recommend completing both registrations, using Nexora AI and AgriGuide as your starting point.

1. BASIX State of the Art Hackathon
State of the Art Hackathon

Registration deadline: October 16, 2026, at 5:59 PM EAT

Team size listed: 3–4 members

Registration:
BASIX.MARKET registration

Step 1 — Create or join a team

Choose Create a new team.

Field

Enter/select

Team name

Nexora AI

Team size

Track

Omega AI Agents

Challenge

The Glass Box Agent

Project stage

Working prototype

GitHub repository

https://github.com/Edwin420s/

The repository link above is your GitHub profile, not a direct project repository. If AgriGuide is in a specific repository, use that repository's URL instead.

Step 2 — Problem description

Use this for “Which problem are you solving?”

Writing

AI agents can make recommendations without providing a clear, verifiable account of how they reached their conclusions. This makes it difficult for users to understand, trust, and challenge their decisions.

Nexora AI is extending AgriGuide, an agricultural decision-support platform that combines weather forecasts, sensor readings, and farmer observations to help farmers decide whether to irrigate, wait, or reassess. Using Omega's stateful agent architecture and MeTTa-based reasoning, AgriGuide maintains a traceable decision history, explains the evidence and rules behind recommendations, and records how decisions change when new information arrives.

The goal is to demonstrate an auditable AI agent whose decisions can be inspected, compared against new evidence, and evaluated against observed outcomes.

Why I recommend this combination

Track: Omega AI Agents — directly matches your previous Omega experience.

Challenge: The Glass Box Agent — best fits AgriGuide's explainable reasoning and audit trail.

Stage: Working prototype — appropriate for the existing AgriGuide build, provided the repository demonstrates those features.

Important: The registration page explicitly requires at least three team members and says there is no solo path. Since you have already contacted the organizers about participating alone, proceed with the team creation if the form allows it, but don't invent teammates or misrepresent your team size. If it blocks submission, ask the organizers to apply the exception they discussed with you.

2. AI Omega Developer Buildathon — Lisbon
AI Omega Developer Buildathon

Lisbon, Portugal · Free registration, subject to approval

Official event:
Open the Luma event

Which date should you choose?
My recommendation
Week 2 — October 29–30

Fintech House, Unicorn Factory Lisboa · 10:30 AM–5:00 PM each day

Choose this session because it gives you several extra days to arrange travel, accommodation, and event approval compared with the October 23–24 session. It also leaves more time to prepare a polished AgriGuide demonstration.

Week 1 is October 23–24 at HealthHub, Unicorn Factory Lisboa. Both sessions require approval and have limited seats.

What to do on Luma

Select Week 2: 29 to 30 October.

Click Accept Invitation or Request to Join, depending on what the page displays.

Complete any requested details and submit the registration.

Wait for approval and confirmation of the venue.

One important practical consideration: the event is in Portugal, and a free ticket does not mean travel, accommodation, or visa costs are covered. Confirm that you can travel before making non-refundable bookings.

Your strongest strategy is to use AgriGuide as the flagship project across both opportunities, emphasizing the specific Omega integration, MeTTa reasoning, decision audit trail, and outcome-based learning that you can actually demonstrate.

The Challenge option "Choose a challenge

Two Agents One Truth

The Agent Without Borders"

BASIX.MARKET - Mature Build

For your Nexora AI — AgriGuide project, choose:

Challenge: BASIX.MARKET – Mature Build

Why: AgriGuide already has a working-prototype foundation from your previous Omega hackathon. This challenge option is the best fit if you want to develop that existing project further rather than start from scratch.

Your registration should be:

Team name: Nexora AI

Track: Omega AI Agents

Challenge: BASIX.MARKET – Mature Build

Project stage: Working prototype

Project: AgriGuide

Backup option: The Agent Without Borders if you decide to focus primarily on cross-border, multilingual, or globally accessible agent capabilities.

I would choose BASIX.MARKET – Mature Build for the strongest continuity with your existing work.

Given this updated direction, I’d position Nexora AI — AgriGuide as the project you carry forward, but I would make one important distinction before submitting the BASIX registration.

My recommendation

Project: AgriGuide

Team: Nexora AI

Track: Omega AI Agents

Challenge: BASIX.MARKET – Mature Build

Stage: Working prototype, if that accurately reflects the current build.

Mature Build makes sense if the challenge is intended for teams extending an existing product. Your fifth-place finish and working prototype give you a credible foundation, so improving AgriGuide is more sensible than rebuilding an unrelated idea from scratch.

However, don't assume that the previous fifth-place finish was specifically an Omega-powered win or that AgriGuide already implements MeTTa reasoning and a full audit trail unless you can demonstrate those features.

What AgriGuide should demonstrate

1. Evidence-based decisions: use available weather, soil, crop, and farmer-provided data.
2. Explainability: show why the system recommends irrigating, waiting, or gathering more information.
3. Auditable history: preserve the inputs, recommendation, reasoning evidence, and changes over time.
4. Evaluation: test recommendations against known rules and recorded outcomes, rather than treating an AI agent's confidence as proof.

For the BASIX challenge, confirm that Mature Build accepts your current project stage and that the organizers' team-size requirements are satisfied.

For the Lisbon Developer Buildathon, keep the registration separate. Week 2, October 29–30, remains the more practical choice if you can arrange travel to Portugal, since the event ticket does not itself cover travel or accommodation.

One final strategic point: your registration and your actual deliverable should tell the same story. Build on AgriGuide's working features first, then add only the Omega-specific capabilities you can implement and demonstrate before the deadline.

i think that for the agriduide will not meet the requirements for the hackathon , "

Live nowDay 1 of 4Online18 Oct, 10:30 — 21 Oct 2026, 23:59 GMT+3

State of the Art Hackathon

A hackathon for artists, musicians and builders, run with SingularityNET and Omega. Pick one of four tracks, form a team of 3 to 4 (or find one on the BASIX job board), and build something BASIX can incubate. Builders submit a GitHub repo shared with BASIX.MARKET; creators submit the finished piece. Everyone submits short documentation with an AI disclosure and a 3-minute video. Judged on technical or creative execution (30%), video and demo clarity (25%), fit to track (25%), and team collaboration and documentation (20%). Prize pool: $1000.

1.

, this are the rules attached above

After reviewing the hackathon rules you shared, your concern about AgriGuide is reasonable. I would not force AgriGuide into a challenge that it doesn't naturally satisfy. But you don't necessarily have to abandon it, either.

The most important detail is on page 11 of the rules: Track 03, Hack Ready Projects, is specifically for builders bringing an existing project to expand. Judges score only the new work completed during the hackathon, not the project's existing features.

Pasted text(20261018-184715).txt

That makes the choice clearer: you can either adapt AgriGuide to a specific challenge with a substantial new feature, or use the already-registered ClearTrace Labs entry to build something designed around the challenge from the start.

Why AgriGuide is a weaker fit for your current entry

The rules distinguish the challenges quite clearly.

Pasted text(20261018-184715).txt

Challenge	What the rules expect	Fit for your projects
Two Agents, One Truth	Two agents evaluate contradictory inputs and work toward a shared conclusion	ClearTrace Labs
The Agent Without Borders	Agents handle diverse languages, literacy levels and low connectivity	AgriGuide only if you build those capabilities

BASIX.MARKET — Mature Build	A production-ready functional module for the BASIX NFT marketplace	Neither project fits naturally without a substantial change

The rules also describe a separate Hack Ready Projects open track for existing projects, where only new work completed during the hackathon is scored. However, your current registration is under Omega AI Agents, so don't assume you can switch to that track after registration has closed.

Pasted text(20261018-184715).txt

My recommendation: continue with ClearTrace Labs

Since you're already registered with ClearTrace Labs, I would keep that project and choose Two Agents, One Truth.

Make the core demonstration small and concrete:

1. Agent A independently analyzes an invoice or other business record.
2. Agent B independently analyzes the corresponding purchase order or supporting record.
3. A verification layer identifies conflicting values and checks them against the original evidence.
4. The agents produce a final reconciliation report showing what agrees, what conflicts, and what remains unresolved.

One caution: the challenge's example focuses on reconciling conflicting community accounts of a historical event. A financial-records use case follows the general two-agent concept, but may be less aligned with that example. Make the shared reasoning, evidence and resolution of contradictions the central feature, and verify the intended domain with the organizers if possible.

You have until Tuesday, October 20, at 5:59 PM EAT to submit. Your highest priority should be a functioning end-to-end demo, a clean GitHub repository, concise documentation with AI disclosure, and a three-minute video.

Pasted text(20261018-184715).txt

Bottom line: don't rebuild AgriGuide just to force it into this challenge. Keep AgriGuide for a future agriculture-focused opportunity and concentrate on making ClearTrace a convincing, verifiable two-agent system for this hackathon.

Problem

Two Agents One Truth

Stage

Just an idea

https://github.com/Edwin420s

Which problem you're solving

Small businesses increasingly use AI tools to assist with operational decisions, but it can be difficult to verify the evidence behind an AI-generated recommendation or reconstruct what the system did. ClearTrace addresses this trust and accountability gap by building an AI agent that reviews supplier invoices against purchase-order records, identifies discrepancies, explains findings using traceable evidence, proposes corrective actions, and records user approvals and agent activity in an auditable log. The goal is to make AI-assisted workflows more transparent, reviewable, and controllable.

Team details are locked now that the hackathon has begun.

Home — BASIX Omniversity Incubator

" never registered for the agriduide was trying to see if it can fit but we can continue with the old one project and wirk with it fully to meet all the requirements on them

You're right — you registered ClearTrace Labs, not AgriGuide. AgriGuide was only an existing project you were considering, to see whether it could fit the hackathon. We can leave AgriGuide aside and continue with the project you actually registered.

My recommendation is to build ClearTrace properly around the exact challenge you selected: “Two Agents One Truth.” We should use the time available to turn your idea into a working, demonstrable product, not just a concept or a polished description.

1. What we need to deliver

A working GitHub repository

The actual application, setup instructions, sample records, tests, and documentation — not just your GitHub profile link.

Two genuinely distinct agents

Each independently examines the evidence. A reconciliation step identifies agreements, disagreements, and claims that cannot be verified.

Evidence-based results

Users can see the original invoice and purchase order, the fields that match or conflict, why a discrepancy was flagged, and what still needs human review.

A usable demo and submission

A working interface, a short README and AI disclosure, and a clear three-minute demo video.

One important distinction: two agents agreeing does not automatically make a claim true. ClearTrace should check their conclusions against the source records and explicitly show unresolved conflicts. That will make the product more credible.

2. The two issues we must solve first

Issue 1 — Team eligibility. Your registration page says the minimum is three members, but you currently have one. It also says registration is closed and the invite code is no longer joinable. This is a serious submission risk. Contact the organizers through the BASIX help desk on Telegram and ask whether they can manually add two members or grant an exception. We can build while waiting, but we should not assume a solo submission will be accepted.

Issue 2 — Challenge alignment. Your current invoice-versus-purchase-order idea is useful, but we need to make sure it satisfies the actual Two Agents One Truth brief. I tried opening the linked slide deck, but it did not load. I don't want to claim we have met requirements we haven't verified.

3. The development plan for ClearTrace

Phase 1 — Confirm the challenge and eligibility

Check the specific challenge requirements, the expected use of Omega, and whether your team can submit with an exception.

Phase 2 — Build the core workflow

Upload or enter an invoice and purchase order; run Agent A and Agent B independently; compare their findings against the original evidence; and show agreements, discrepancies, and unresolved questions.

Phase 3 — Make it trustworthy

Include evidence references, an auditable activity log, human approval for corrective actions, error handling, and tests for matching and conflicting records.

Phase 4 — Prepare the submission

Create the repository, installation instructions, architecture documentation, AI-use disclosure, sample data, and a three-minute demo showing a complete successful run.

4. What I need from you next

Please upload the hackathon rules and brief as a PDF or screenshots of the relevant slides, especially the slide describing Two Agents One Truth and any technical requirements for Omega. That will let us design against the actual judging criteria instead of guessing.

We'll keep the registered name ClearTrace Labs and work from your existing description. We won't switch to AgriGuide or invent a different project. The priority is to make ClearTrace genuinely functional, aligned with the challenge, and ready to submit before the deadline — while resolving the team-minimum issue in parallel.

for issue one they are allowing the team of 1 so that is not the issue at all , let first define the all of the problem we had discuused ealier before bringing the agriguide

You're right. The team-size issue is settled: BASIX allows a team of one, so we will not treat that as a blocker. We should first define the complete problem and scope of ClearTrace Labs, based on what we had already discussed, before considering AgriGuide or making any changes to the project.

Our starting point is the project you registered under Omega AI Agents → “Two Agents One Truth.” The original idea was to build an AI system that makes operational decisions more transparent, verifiable, and auditable, starting with supplier invoices and purchase orders.

1. The original problem we were solving

Businesses increasingly use AI to help with operational decisions, but trusting an AI-generated answer is difficult when a user cannot see the evidence behind it, verify whether its claims are correct, or reconstruct how it reached its conclusion.

For example, a business might receive a supplier invoice claiming that 100 units were delivered at KSh 500 per unit. The purchase order might specify 90 units at KSh 500 per unit.

A conventional AI assistant might summarize the invoice, overlook the discrepancy, or confidently recommend payment without showing the underlying evidence.

The deeper problem is not simply invoice processing. It is how to establish, verify, and explain the truth when AI agents independently examine information and may reach different conclusions.

ClearTrace Labs was intended to address that problem by having agents examine the records, compare their findings against the original evidence, explain disagreements, and keep a record of what happened.

2. The complete problem definition

ClearTrace Labs — Problem Statement

Small businesses increasingly rely on AI to review business records and recommend actions. However, AI-generated findings can be incorrect, incomplete, inconsistent, or difficult to verify. When two AI agents analyze the same information, their conclusions may differ, and agreement between them does not necessarily mean either conclusion is correct.

Businesses need a system that allows AI agents to examine evidence independently, exposes agreements and disagreements, checks claims against original records, explains every finding, identifies uncertainty, and preserves an auditable history of decisions and human approvals.

This breaks down into several connected problems.

Problem A: AI-generated claims are difficult to verify

An AI agent may say that an invoice is correct, a supplier charged the wrong amount, or a purchase order supports a payment.

But the user needs to know:

- Which original document supports the claim?
- Which field, amount, date, or line item was examined?
- Was the value extracted correctly?
- Does the claim match the source record?
- Is there enough evidence to reach a conclusion?

What ClearTrace must solve: Every important finding should be traceable to the underlying evidence rather than presented as an unsupported AI answer.

Problem B: Independent agents can disagree

Two AI agents may examine the same invoice and purchase order but produce different results.

For example:

- Agent A reports that the invoice total matches the purchase order.
- Agent B reports that the quantities differ.
- A third mechanism must determine whether the difference is real, caused by an extraction error, or cannot yet be resolved.

What ClearTrace must solve: It must make differences between agents visible and explain them instead of silently choosing one agent's answer.

Problem C: Agreement between agents does not establish truth

Two agents can make the same mistake. They might both misread a number, overlook a line item, or rely on the same incorrect assumption.

What ClearTrace must solve: The system needs an independent verification layer that checks extracted claims against the original records and applicable business rules. Agent agreement is useful evidence, but it is not proof.

Problem D: Conflicting records are difficult to resolve

Even correctly extracted records can disagree. An invoice may contain a different quantity, price, supplier name, reference number, or date from the corresponding purchase order.

Some differences may be legitimate, while others require correction or investigation.

What ClearTrace must solve: It should distinguish between verified matches, genuine discrepancies, uncertain findings, and cases requiring human review. It should not assume that every difference is fraud or automatically decide which document is authoritative.

Problem E: AI decisions lack a complete audit trail

A user may see a final recommendation without being able to reconstruct the process that produced it.

Important information can be missing, including what documents were provided, what each agent reported, which checks were performed, what discrepancies were found, and who approved the proposed action.

What ClearTrace must solve: It should maintain an audit history that records the evidence, agent findings, verification results, proposed actions, human decisions, and relevant timestamps.

Problem F: Recommended actions can be taken without sufficient oversight

An AI agent might recommend paying an invoice, contacting a supplier, or correcting a business record. Acting on that recommendation without checking the evidence can cause financial loss or operational errors.

What ClearTrace must solve: The initial system should recommend corrective actions and explain why they are appropriate, while requiring human approval before consequential actions are carried out.

3. Who experiences the problem?

The initial target users are small businesses that handle supplier invoices, purchase orders, and related operational records.

Small-business owners and operators

Need confidence that business records have been checked properly before approving payments or making operational decisions.

Finance and accounts staff

Need to identify incorrect amounts, quantities, references, and other inconsistencies without manually comparing every field.

Managers and auditors

Need evidence for findings, clear explanations of disagreements, and a record of who reviewed and approved a decision.

These are the initial users for the invoice-and-purchase-order use case. The broader verification approach could eventually support other business workflows, but we should not expand the first version unnecessarily.

4. What ClearTrace Labs is intended to build

The previously discussed solution has five core components.

1. Evidence intake

Accept an invoice, its corresponding purchase order, and relevant supplier information. Extract the important fields while preserving references to their original sources.

2. Two independent agents

Agent A and Agent B examine the records independently. Each produces structured findings, explanations, and uncertainty indicators without simply copying the other agent's conclusion.

3. Evidence verification and reconciliation

Compare both agents' findings with the original records. Identify agreements, disagreements, mismatches, unsupported claims, and unresolved questions.

4. Explainable review interface

Show the user what matched, what did not, why it matters, the evidence behind the finding, and what action is proposed.

5. Human approval and audit history

Let an authorized user review the findings, approve or reject the proposed action, and inspect the recorded sequence of events.

5. How the complete workflow should work

This is the product workflow we had been moving toward, from the user's first interaction to the final recorded decision.

A few details are important to this workflow:

- Extraction is not verification. A field being extracted successfully does not establish that its value is correct.
- Agent comparison is not source validation. The system must check the original invoice and purchase order.
- Uncertainty must be an outcome. If evidence is missing or ambiguous, the system should say so rather than invent a confident answer.

- Approval must be explicit. A recommendation is not the same as an approved business action.
- The audit history must be meaningful. It should capture the sequence of events, not merely store the final answer.

6. What the system needs to inspect

The first version should compare relevant fields across the invoice, purchase order, and supplier record.

Field	What ClearTrace checks
Supplier identity	Whether the supplier matches the expected business record
Invoice number	Whether the invoice reference is present and consistent
Purchase-order reference	Whether the invoice points to the correct order
Item or SKU	Whether the billed items correspond to ordered items
Quantity	Whether the billed quantity matches the ordered quantity, allowing for documented exceptions
Unit price	Whether the billed price matches the agreed price
Subtotal and total	Whether line calculations, taxes, and totals are internally consistent
Currency	Whether amounts use the expected currency

Dates	Whether invoice, order, and other relevant dates are consistent
Missing information	Whether a conclusion cannot be reached because required evidence is absent

The system should also distinguish a confirmed discrepancy from a possible discrepancy. For example, an invoice quantity that differs from the purchase order is a mismatch between records, but it does not by itself prove that the supplier acted dishonestly. A delivery note or an approved order amendment might explain it.

7. What the user should see at the end

The main result should be an understandable review report rather than a wall of AI-generated text.

Illustrative ClearTrace review

Human review required

Example data only — not a live analysis.

Purchase order

90 units

KSh 500 per unit

Supplier invoice

100 units

KSh 500 per unit

Quantity discrepancy

The invoice lists 10 more units than the purchase order. At the stated unit price, the difference is KSh 5,000 before any applicable tax or adjustment.

Evidence to inspect

The invoice quantity field, the corresponding purchase-order line, and any delivery record or approved amendment that could explain the difference.

Agent findings

Display Agent A's result and Agent B's result separately, including whether they agree and whether their claims are supported by the source records.

Proposed next step

Request verification of the additional quantity before approving payment. Record the human reviewer's decision and any supporting explanation.

This example demonstrates the product's intended value: it does not just say that an invoice is wrong. It shows the discrepancy, its financial implication, the evidence that supports the finding, what remains uncertain, and what the user can do next.

8. The principles that must govern the product

These principles follow from the original problem and should guide both implementation and evaluation.

1. Evidence before conclusions. Findings should point to the underlying records.
2. Independent analysis. The agents should be meaningfully distinct in their analysis, not two labels for the same result.
3. No automatic trust in consensus. Both agents can be wrong.
4. Visible disagreement. Conflicts should be preserved and explained rather than hidden.
5. Honest uncertainty. Missing, ambiguous, or contradictory evidence should remain unresolved until enough information exists.
6. Human control. Consequential actions should require authorized approval.
7. Auditable activity. The system should record inputs, findings, verification results, decisions, and follow-up actions.
8. Reproducible demonstrations. A reviewer should be able to run the example and see how the system handles both correct records and deliberate discrepancies.

9. What belongs in the first version — and what does not

To keep the project achievable, the first version should focus on the invoice-and-purchase-order use case.

In scope for the MVP

Upload or enter an invoice and its purchase order
Extract and validate key fields
Run two independent agent analyses

Compare agent results against original evidence
Identify matches, discrepancies and unresolved claims
Display evidence-linked explanations and proposed corrective actions
Require human review and record the decision
Maintain an audit history
Include realistic synthetic sample documents and automated tests
Provide setup instructions, architecture documentation and AI disclosure

Not required for the first version

- Fully autonomous payment processing.
- Integrations with every accounting or enterprise resource planning platform.
- Support for every document format and business workflow.
- A claim that the system can eliminate fraud or guarantee truth.
- A complex multi-agent network that adds features without improving verification.

The first version must be genuinely functional, not just a mock dashboard. A reviewer should be able to submit records, observe two agent analyses, see evidence-backed reconciliation, review a discrepancy, and inspect the resulting audit trail.

10. How we will know whether we have solved the problem

We need to evaluate the product against observable behavior, not simply whether it produces impressive AI responses.

Test	Expected behavior
Matching records	Identifies the relevant fields as matching
Incorrect invoice quantity	Flags the quantity mismatch and calculates the difference correctly
Incorrect unit price	Identifies the price conflict and its financial implication

Agents disagree	Shows both findings and explains the conflict
Both agents make the same mistake	Source-level verification can still expose the error
Evidence is missing	Reports that the claim cannot yet be verified
Supplier record conflicts	Identifies the conflicting information without arbitrarily choosing a winner
Human rejects a recommendation	Records the rejection and reason
User inspects the audit history	Can reconstruct the key stages and decisions
System encounters malformed input	Handles the error without inventing a successful result

These tests should become the acceptance criteria for the implementation and the basis of the demo.

11. What is established, and what still needs confirmation?

We should keep three things separate.

- Established from our earlier discussion: ClearTrace Labs, the Omega AI Agents track, the “Two Agents One Truth” challenge, the invoice-and-purchase-order problem, independent agents, source-level verification, evidence-linked findings, human approval, and audit logging.
- Proposed implementation details: The exact fields, dashboard layout, data model, automated tests, and specific discrepancy examples above. These turn the original concept into a buildable specification.

- Still to verify: The precise technical requirements in the official challenge brief, including whether particular Omega tooling or a specific agent framework is mandatory. We should not claim compliance with requirements we have not checked.

The eventual submission also needs the working GitHub repository, clear setup and architecture documentation, AI disclosure, and a short demonstration video. The challenge-specific requirements should be checked against the official brief before we finalize the architecture.

The definition we should carry forward

ClearTrace Labs is an evidence-first, multi-agent verification system for trustworthy AI-assisted business decisions. Its initial application is supplier invoice and purchase-order review. Two agents independently analyze business records, a verification layer checks their claims against the source evidence, and the system exposes agreements, disagreements, discrepancies, and uncertainty in an explainable report. A human remains in control of consequential decisions, and the process is preserved in an auditable history.

That is the problem and product scope we should define first. We can now refine the requirements and architecture for the project you actually registered, without bringing AgriGuide into it or changing the original idea.

willl this meet hackathon requirements

Yes — ClearTrace Labs is a strong fit for the hackathon's “Two Agents One Truth” challenge, but the problem definition alone does not guarantee that the project will qualify or score well. We need to turn it into a working implementation and confirm any challenge-specific technical requirements.

The official BASIX hackathon listing confirms that the event evaluates projects on technical or creative execution (30%), demo clarity (25%), fit to the selected track (25%), and collaboration and documentation (20%). It also calls for a working GitHub repository, short documentation with an AI disclosure, and a three-minute video.

BASIX Omniversity Incubator
+1

Requirement-by-requirement assessment

Hackathon requirement	How ClearTrace addresses it	Status
Fit the selected challenge	Two agents independently investigate the same business records and reconcile their findings	Strong conceptual fit
Technical execution	Document intake, two agents, evidence verification, reconciliation, and audit history	Must be implemented
Demonstrable working product	Upload records and show a complete review from input to decision	Must be built and tested
Clear demo	Demonstrate matching records, a discrepancy, agent disagreement, and human review	Planned, not yet demonstrated
GitHub repository	Source code, setup instructions, tests, sample data, and architecture	Must be prepared and shared
AI disclosure	Document which AI models and tools are used and what they do	Must be included
Three-minute video	Show the actual product working	Must be recorded
Challenge-specific technical rules	Any mandatory Omega tooling or integration requirements	Still needs confirmation

The general requirements are grounded in the official event listing.

BASIX Omniversity Incubator

I could not retrieve the actual challenge slide deck, so I cannot yet certify compliance with its detailed instructions.

The biggest risk to address

The most important thing is that ClearTrace must be a genuine two-agent verification system, not simply an invoice checker with two AI labels.

For a compelling implementation:

1. Agent A independently extracts and analyzes the invoice and purchase order.
2. Agent B independently analyzes the same source records using a distinct approach.
3. A separate verification layer checks their claims against the original evidence and deterministic business rules.
4. The system shows agreements, disagreements, discrepancies, and unresolved claims.
5. The user reviews the evidence and approves or rejects the proposed next step.

That is what will make the project meaningfully aligned with the challenge rather than just another AI-powered document-processing application.

What I recommend

Build the MVP around one complete, reproducible scenario: a purchase order for 90 units and an invoice for 100 units, with a clear explanation of the 10-unit discrepancy. Then demonstrate a matching case and a case where the agents disagree. Include tests showing that the verification layer can catch an error even when both agents agree.

Before locking the architecture, we still need to inspect the official “Two Agents One Truth” brief. You can upload the relevant slides as a PDF or screenshots here, particularly the challenge description and any mandatory Omega requirements.

My verdict: the concept is suitable and promising, and the scope we defined is a good foundation. Whether it meets all hackathon requirements depends on implementing the working system, completing the submission deliverables, and checking the challenge-specific rules.
